Campaign Overview

Operation Ghost was a long-running cyber espionage campaign carried out by a Russian hacking group known as APT29, also called Cozy Bear. It ran from around 2013 to 2019 and mainly targeted European foreign ministries and diplomatic organizations, including an EU embassy in Washington, D.C.

Unlike typical cyberattacks that aim to steal money or cause damage, this operation was focused on quietly gathering intelligence over time.

What made Operation Ghost stand out was how carefully everything was customized. The attackers didn't just reuse the same tools everywhere—they created different malware setups and communication methods for each target. Because of this, it was much harder for security systems to detect any patterns.

The attack usually started with reconnaissance. The hackers studied their targets in detail—how they communicated, what kind of documents they used, and how their systems worked. Then came spear-phishing emails that looked extremely convincing, often related to political topics, NATO discussions, or diplomatic events.

Once someone opened the malicious file, a small piece of malware would be installed first. Tools like RegDuke or PolyglotDuke were used to quietly gain access without raising suspicion. These acted as a gateway, bringing in more advanced malware only if the system was considered valuable.

Later, stronger tools like MiniDuke were deployed to maintain access. In high-value cases, they even used a more powerful implant called FatDuke, which allowed long-term surveillance and data collection.

One of the most clever techniques used in Operation Ghost was steganography. Instead of sending obvious malicious data, the attackers hid their instructions inside normal-looking image files like GIFs or PNGs. So to anyone monitoring the network, it just looked like regular image traffic.

They even used platforms like Twitter for communication. The malware would scan for specific tweets containing hidden instructions or links, making the activity blend in with normal social media usage.

To stay inside systems for a long time, the attackers relied on techniques like WMI-based persistence, which allowed their malware to restart automatically without being noticed. They also moved across networks using stolen credentials and legitimate tools like PsExec, avoiding detection by acting like normal system administrators.

Overall, Operation Ghost is a classic example of how advanced cyber espionage works. Instead of being loud or destructive, it focused on staying hidden, maintaining access, and collecting valuable information over long periods.

Threat Actor/Group Association

The campaign has been attributed to APT29, a highly sophisticated state-sponsored threat actor group known for cyber espionage. The group is centered around long-term, stealthy operations, with the aim of intelligence gathering rather than immediate impact.
APT29 is known to use encrypted and covert channels of communication, and to develop bespoke malware for each stage of an attack. They don't rely on one tool, they use layers of tools, they deploy light-weight initial malware, and only if the target is valuable do they move to more advanced backdoors.

In Operation Ghost, APT29 displayed strong operational discipline by using separate infrastructure for each victim, including unique domains and command-and-control servers. This made it very difficult for defenders to spot patterns or correlate attacks. They also used techniques such as hiding malicious traffic in normal data (like images or web traffic), allowing them to remain undetected for long periods of time.

This campaign overall shows APT29's precision, patience and emphasis on invisibility while continuously siphoning sensitive diplomatic information.

Timeliness

First Seen: **September 2013**
Last seen: **October, 2019**
The extended timeline shows that attackers were able to maintain persistence in target environments for a number of years.
These long durations suggest:

- Targeted systems with poor detection capabilities
- Attacker patience and planning level high
- Ongoing changes in attack techniques over time

Overall, this duration proves that Operation Ghost was not a one-time attack, but a sustained and carefully managed espionage operation focused on silently extracting sensitive information over the long term

Objectives of Attack

Operation Ghost's primary operational goal was cyber espionage, with a specific emphasis on strategic intelligence collection, not disruption or financial gain.

Key goals were:

- Gathering sensitive diplomatic and government information
- Tracking internal communications and policy discussions
- Keeping long-term hidden access to critical systems

In addition to collecting information from all levels of government, attackers were also trying to passively monitor how decisions are made within government ministries and embassies. By remaining on the networks for extended periods, the attackers could collect information related to Geopolitical developments, diplomatic exchanges, and confidential transactions in real-time, enabling them to maintain an ongoing intelligence advantage over possible adversaries rather than just onetime data theft.

In terms of persistence, the attackers were also attempting to maintain the same level of persistence while remaining undetected. Rather than extracting large amounts of data in a single event, the attackers employed controlled and gradual exfiltration techniques, so the attackers did not raise any suspicion of their continued presence as long they could keep from being discovered.

Unlike financially motivated cyberattacks, Operation Ghost was an extremely well thought-out and tactical cyberattack. Every part of the operation - including the use of custom malware and stealthy communications - served to support long-term intelligence gathering and passive surveillance, signalling very strong indications of potential state-level geopolitical intentions, versus opportunistic cybercrime.

Targeted Sectors/Countries Attack Flow

The objective of Operation Ghost was to compromise the diplomatic and governmental sectors.
Operation Ghost specifically targeted the following areas of attack:

- The Ministry of Foreign Affairs in various European nations
- Diplomatic missions/embassies around the world
- National governmental telecommunications systems

One verified victim of Operation Ghost included the embassy of one of the European Union states located in Washington, D.C. In conclusion, the majority of the data compromised through Operation Ghost came from European diplomatic institutions displaying a keen interest in geo-political and international relations information by those behind the operation.

The targeted sectors indicate that the operation was designed to gather:

- Foreign policy information
- Diplomatic communications
- Strategic government intelligence
- International negotiation details

Attack Flow of Operation Ghost:

The attack followed a structured and layered approach:

Step 1: Infrastructure Preparation: Attackers registered malicious domains that closely resembled legitimate ones.

- This helped them avoid suspicion during initial communication.
- In addition, separate infrastructure was created for each target, including unique domains and servers, which reduced the chances of detection and made tracking the campaign extremely difficult.

Step 2: Initial Access: Victims were targeted using crafted links or compromised platforms.

- The goal was to trick users into interacting with attacker-controlled resources.
- These links were often delivered through highly targeted spear-phishing emails that appeared relevant to diplomatic or political topics, increasing the success rate.

Step 3: Malware Deployment: Custom malware such as PolyglotDuke and MiniDuke were introduced into the system.

- These acted as entry points and downloaders for further payloads.
- The attackers used a staged approach, meaning only lightweight malware was deployed initially, while more advanced tools were delivered later based on the importance of the target.

Step 4: Establishing Persistence: APT29 used Windows Management Instrumentation (WMI) event subscriptions.

- This ensured that malware remained active even after system reboots.
- This technique also allowed attackers to execute code in a stealthy way, avoiding traditional detection mechanisms like startup programs or scheduled tasks.

Step 5: Command and Control Communication: Communication with attacker servers was hidden using:

  - Social media platforms
  - Web-based services

- This made malicious traffic look like normal internet activity.
- In some cases, encrypted instructions were embedded within normal-looking content, allowing malware to receive commands without raising alerts.

Step 6: Data Collection and Exfiltration: Sensitive data was collected and transmitted secretly using obfuscation techniques like steganography.

- This allowed attackers to hide data inside images or normal files.
- Instead of sending large amounts of data at once, exfiltration was done gradually, ensuring long-term access remained undetected.

Step 7: Long-Term Surveillance: After successful exfiltration, attackers continued monitoring the systems.

- This allowed continuous access to diplomatic communications and strategic information.
- Rather than exiting after data theft, APT29 maintained a silent presence, turning the compromised systems into long-term intelligence sources.

MITRE ATT&CK

Operation Ghost relied on multiple advanced techniques mapped in the MITRE ATT&CK framework:

1. **T1583.001** – Acquire Infrastructure (Domains) Attackers registered fake domains to host malicious infrastructure.
- These domains closely mimicked legitimate diplomatic or government websites, increasing trust and reducing suspicion.

2. **T1001.002** – Data Obfuscation (Steganography)

Data and communication were hidden inside images to avoid detection.
- This allowed malicious data to blend into normal traffic, bypassing traditional security monitoring systems.

3. **T1587.001** – Develop Capabilities (Malware)

Custom malware tools were developed specifically for this campaign.
- Different malware families were used at different stages, showing a modular and highly planned attack design.

4. **T1585.001** – Establish Accounts (Social Media)

Fake social media accounts were used as communication channels.
- These accounts acted as indirect command sources, making traffic look completely normal.

5. **T1546.003** – Event Triggered Execution (WMI)

Used to maintain persistence within systems.
- Enabled malware to execute automatically based on system events without raising alerts.

6. **T1027.003** – Obfuscated Files

Malware payloads were disguised to bypass security tools.
- This reduced detection by antivirus and endpoint protection systems.

7. **T1078.002** – Valid Accounts

Stolen credentials were used for lateral movement.

- Attackers accessed systems as legitimate users, making their actions harder to distinguish from normal activity.

8. **T1102.002** – Web Service Communication

Web platforms were used for command and control.

- Leveraging trusted services helped hide malicious communication within regular internet usage.

Real-World Incidents

Operation Ghost is linked to real-world cyber espionage activities carried out by APT29, targeting diplomatic institutions and government organizations.

One of the key incidents associated with this campaign involved attacks on ministries of foreign affairs across Europe. These institutions handle highly sensitive diplomatic communications, making them valuable targets for intelligence gathering.

Another significant incident was the compromise of an embassy located in Washington, D.C. In this case, attackers successfully infiltrated the network and maintained long-term access without being detected. This allowed them to monitor internal communications and potentially extract confidential information over an extended period.

The campaign also demonstrated the use of advanced techniques such as steganography and social media-based command-and-control communication in real-world environments. These methods made it extremely difficult for traditional security systems to identify malicious activity.

From an analytical perspective, these incidents highlight how modern cyber espionage campaigns are not focused on immediate damage, but rather on silently collecting intelligence over time. Operation Ghost serves as a strong example of how attackers can remain hidden within critical systems for years while continuously extracting valuable information.

Detection Opportunities

Detection can be achieved by monitoring:

- **Suspicious domain registrations:** Look for newly registered domains that closely resemble legitimate government or diplomatic websites. Sudden communication with such domains can indicate attacker-controlled infrastructure.

- Hidden data within image files: Analyze image traffic for anomalies such as unusual file sizes, repeated downloads, or embedded data patterns, which may indicate steganography-based communication.

- Abnormal WMI activity: Monitor for unexpected or unauthorized Windows Management Instrumentation (WMI) event subscriptions, as these are often used for stealthy persistence.

- Unusual use of social media for communication: Detect systems making automated or background requests to social media platforms, especially if they are not typically used in organizational workflows.

- Unauthorized access using admin credentials: Identify login attempts from unusual locations, odd timings, or inconsistent behavior patterns that may indicate compromised credentials.

Beyond these, effective detection also requires behavior-based monitoring rather than relying only on signature-based tools. Since Operation Ghost used highly customized malware, traditional antivirus solutions may fail to detect it. Network traffic analysis can help identify low-volume but consistent data exfiltration patterns

User behavior analytics (UBA) can detect deviations in normal user activity Endpoint monitoring can reveal suspicious process executions and hidden persistence mechanisms. Overall, detecting such campaigns requires a shift from reactive security to proactive threat hunting, because attackers like **APT29** don't make obvious mistakes—they blend into normal system activity and stay there quietly for years.

Defensive Recommendations

To defend against such campaigns:

- **Deploy advanced endpoint detection tools**: Use EDR/XDR solutions that focus on behavior analysis, not just signatures, to detect stealthy and custom malware.

- **Monitor network traffic for anomalies**: Identify unusual outbound connections, low-volume data exfiltration, and communication with unknown or suspicious servers.

- **Restrict and audit user privileges**: Apply the principle of least privilege and regularly audit admin accounts to prevent misuse of valid credentials.

- **Detect and block suspicious domains**: Use DNS monitoring and threat intelligence feeds to identify and block lookalike or newly registered malicious domains.

- **Monitor WMI and scripting activities**: Track abnormal use of WMI, PowerShell, or other scripting tools that may be used for persistence or lateral movement.

- **Educate users about phishing and social engineering:** Train employees to recognize targeted phishing attempts, especially those related to official or diplomatic topics.

Conclusion

Operation Ghost stands as a prime example of a highly advanced cyber espionage campaign. Its use of stealth techniques, customized malware, and long-term persistence clearly highlights how modern cyber threats have evolved beyond traditional, short-term attacks.

The campaign demonstrates how attackers prioritize remaining undetected while continuously gathering intelligence over extended periods. By using tailored infrastructure, layered malware, and covert communication methods, they were able to maintain access and monitor sensitive diplomatic environments for years.

From a cybersecurity perspective, Operation Ghost emphasizes the critical need for proactive detection, continuous monitoring, and strong defensive strategies. It also underlines the importance of behavior-based analysis, user awareness, and strict access control in defending against such sophisticated threats.

In conclusion, this campaign is not just an example of an attack—but a model of how modern cyber espionage operations are carefully planned, executed, and sustained with precision.

Software Research (from S0001 to S0010)

This report focuses on software within the ID range S0001 to S0010 from the MITRE ATT&CK framework. These tools include a mix of malware, RATs, and post-exploitation utilities used by threat actors for persistence, credential access, command and control, and data exfiltration.

1. Duqu (S0001)

- **Name & Type**: Duqu – Malware (Spyware / Information Stealer)

- **Description**: Duqu is a sophisticated espionage malware designed to collect sensitive information from targeted systems. It is known for its modular architecture and stealth capabilities, allowing it to remain undetected while gathering intelligence.

- **Threat Actor Association:** Associated with state-sponsored actors linked to the creators of Stuxnet (not Lazarus Group).

- **Supported Platforms**: Windows

- **ATT&CK Techniques Used:**
  - T1005 – Data from Local System
  - T1059 – Command and Scripting Interpreter

- **Execution Method:**
  - Delivered via spear-phishing emails
  - Malicious document attachments exploiting vulnerabilities

- **Persistence Techniques:**
  - Registry key modifications
  - Installation of hidden services

- **Privilege Escalation:** Exploits system vulnerabilities to gain higher privileges

- **Defense Evasion**:
  - Encrypted payloads
  - Obfuscated code to avoid antivirus detection
- **Credential Access:** Keylogging to capture user credentials

- **Discovery Techniques:** Collects system information such as OS details, files, and configurations

- **Lateral Movement:** Limited, mainly focused on data collection rather than spreading
- **Command & Control (C2):** Communicates with attacker servers using HTTP/HTTPS

- **Exfiltration:** Sends collected data in encrypted form to remote servers

- **Impact Analysis:**
  - Theft of sensitive organizational and personal data
  - Enables long-term surveillance of targeted systems
  - Supports cyber espionage operations

- **Indicators of Compromise (IOCs):**
  - Unknown or suspicious services running in the background
  - Presence of unusual drivers or DLL files
  - Unexpected outbound network traffic

- **Detection & Mitigation:**
  - Monitor abnormal system and network activity
  - Use advanced antivirus/EDR tools
  - Apply regular security updates and patches
  - Restrict execution of unknown files and disable macros

- **References & Sources:** MITRE ATT&CK

2. Mimikatz — S0002

- **Name & Type**: Mimikatz – Post-exploitation Tool / Credential Dumper

- **Description:** Mimikatz is a powerful open-source tool used to extract plaintext passwords, hashes, PINs, and Kerberos tickets from memory. It is widely used by attackers after initial compromise.

- **Threat Actor Association**: Used by multiple threat groups including APT28 and APT29.

- **Supported Platforms:** Windows

- **ATT&CK Techniques Used:**
  - T1003 – OS Credential Dumping
  - T1550 – Use of Alternate Authentication Material

- **Execution Method:**
  - Executed manually after gaining system access
  - Delivered via malware or attacker tools

- **Persistence Techniques: Not primarily used for persistence**

- Privilege Escalation: Requires administrative privileges to access sensitive memory

- **Defense Evasion:**
  - Runs in memory to avoid detection
  - Can bypass some security controls

- **Credential Access:** Dumps credentials from LSASS memory

- **Discovery Techniques:** Identifies authentication mechanisms and system info

- **Lateral Movement**: Enables movement using stolen credentials

- **Command & Control (C2)**: Not directly used for C2

- **Exfiltration:** Extracted credentials sent to attacker

- **Impact Analysis:**
  - Full system compromise
  - Enables further attacks inside network

- **Indicators of Compromise (IOCs):**
  - Suspicious LSASS access
  - Unusual privilege escalation
  - Presence of mimikatz-related binaries

- **Detection & Mitigation:**
  - Monitor LSASS access
  - Enable Credential Guard
  - Use EDR tools

- **References & Sources:** MITRE ATT&CK

3. BlackEnergy (S0003)

- **Name & Type:** BlackEnergy – Malware / Botnet Toolkit

- **Description**: BlackEnergy is a modular malware used for cyber espionage and attacks on critical infrastructure, especially in energy sectors.

- **Threat Actor Association:** Linked to Sandworm Team.

- **Supported Platforms:** Windows

- **ATT&CK Techniques Used:**
  - T1059 – Command Execution
  - T1105 – Ingress Tool Transfer

- **Execution Method**: Phishing emails with malicious attachments

- **Persistence Techniques:**
  - Registry changes

    - Startup execution

- **Privilege Escalation:** Exploits vulnerabilities

- **Defense Evasion:**
    - Obfuscated modules
    - Rootkit capabilities

- **Credential Access:** Can steal credentials

- **Discovery Techniques:** Network scanning

- **Lateral Movement:** Moves within network using stolen credentials

- **Command & Control (C2):** Remote servers via HTTP

- **Exfiltration:** Sends collected data to C2

- **Impact Analysis:**
    - Used in power grid attacks
    - Can disrupt critical infrastructure

- **Indicators of Compromise (IOCs):**
    - Suspicious network traffic
    - Unknown services

- **Detection & Mitigation:**
    - Network monitoring
    - Patch vulnerabilities

- **References & Sources:** MITRE ATT&CK

4. Anchor (S0004)

- **Name & Type:** Anchor – Malware (Backdoor)

- **Description:** Anchor is a stealthy backdoor module associated with TrickBot, designed for covert command and control.

- **Threat Actor Association::** Linked to TrickBot operators.

- **Supported Platforms:** Windows

- **ATT&CK Techniques Used:**
  - T1071 – Application Layer Protocol
  - T1105 – Data Transfer

- **Execution Method:** Delivered via TrickBot infection

- **Persistence Techniques:** Uses parent malware persistence

- **Privilege Escalation:** Uses existing access

- **Defense Evasion:**
  - Encrypted communication
  - Hides traffic

- **Credential Access:** Limited directly

- **Discovery Techniques:** Minimal

- **Lateral Movement:** Supports network spread

- **Command & Control (C2):** Encrypted channels over HTTPS

- **Exfiltration:** Sends data stealthily

- **Impact Analysis:** Enables long-term hidden access

- **Indicators of Compromise (IOCs):** Unusual encrypted traffic

- Detection & Mitigation

- Monitor encrypted outbound traffic
- Use EDR

– **References & Sources:** MITRE ATT&CK

5. ADVSTORESHELL (S0005)

– **Name & Type:** ADVSTORESHELL – Malware (Web Shell)

– **Description:** ADVSTORESHELL is a web shell used by attackers to maintain persistent access to compromised web servers and execute remote commands.

– **Threat Actor Association:** Used by APT29.

– **Supported Platforms:** Web servers (IIS / Windows environments)

– **ATT&CK Techniques Used:**
- T1505 – Server Software Component
- T1059 – Command Execution

– **Execution Method:** Deployed after exploiting web server vulnerabilities

– **Persistence Techniques:** Installed as a hidden web shell on server

– **Privilege Escalation:** Depends on compromised server privileges

– **Defense Evasion:**
- Blends with legitimate web traffic
- Hidden in server files

– **Credential Access:** Can capture credentials via web interactions

– Discovery Techniques: Enumerates server environment

– **Lateral Movement:** Enables access to connected systems

- **Command & Control (C2):** Controlled via HTTP requests

- **Exfiltration:** Sends data through web traffic

- **Impact Analysis:**
  - Full control of web server
  - Long-term hidden access

- **Indicators of Compromise (IOCs):**
  - Unknown files in web directories
  - Suspicious HTTP requests

- **Detection & Mitigation:**
  - Monitor web logs
  - Regular file integrity checks
  - Patch web server vulnerabilities

- **References & Sources:** MITRE ATT&CK

6. NetWire (S0006)

- **Name & Type:** NetWire – Malware (RAT)

- **Description:** NetWire is a remote access trojan that allows attackers to remotely control infected systems and steal sensitive information.

- **Threat Actor Association::** Used by multiple cybercriminal groups

- **Supported Platforms:**
  - Windows
  - Linux
  - macOS

- **ATT&CK Techniques Used:**
  - T1059 – Command Execution

- T1071 – Application Layer Protocol

– **Execution Method:**
  - Phishing emails
  - Malicious downloads

– **Persistence Techniques:**
  - Registry entries
  - Startup programs

– **Privilege Escalation:**
  - Exploits system weaknesses

– **Defense Evasion:**
  - Obfuscated code
  - Encrypted communication

– **Credential Access:**
  - Keylogging
  - Password stealing

– **Discovery Techniques:** Gathers system information

– **Lateral Movement:** Can spread across network

– **Command & Control (C2):** Uses TCP/HTTP communication

– **Exfiltration:** Sends stolen data to attacker

– **Impact Analysis:**
  - Full remote control
  - Data theft

– **Indicators of Compromise (IOCs):**
  - Unknown processes
  - Suspicious outbound traffic

- **Detection & Mitigation:**
  - Use antivirus/EDR
  - Monitor network traffic

- **References & Sources:** MITRE ATT&CK

7. njRAT (S0007)

- **Name & Type:** njRAT – Malware (RAT)

- **Description:** njRAT is a widely used remote access trojan that enables attackers to control systems, log keystrokes, and steal data.

- **Threat Actor Association:** Used by various cybercriminal groups

- **Supported Platforms:** Windows

- **ATT&CK Techniques Used:**
  - T1059 – Command Execution
  - T1005 – Data Collection

- **Execution Method:**
  - Malicious downloads
  - Email attachments

- **Persistence Techniques:** Registry startup entries

- **Privilege Escalation:** Uses system vulnerabilities

- **Defense Evasion:** Obfuscation techniques

- **Credential Access:**
  - Keylogging
  - Credential theft

- **Discovery Techniques:** System and file enumeration

- **Lateral Movement:** Limited

- **Command & Control (C2):** Remote server communication

- **Exfiltration:** Sends stolen data

- **Impact Analysis:**
  - Data theft
  - System compromise

- **Indicators of Compromise (IOCs):**
  - Suspicious registry entries
  - Unknown network connections

- **Detection & Mitigation:**
  - Monitor registry changes
  - Use antivirus

- **References & Sources:** MITRE ATT&CK

8. PIVY (S0008)

- **Name & Type:** PIVY – Malware (RAT)

- **Description:** PIVY is a remote access trojan used for espionage and remote control of infected systems.

- **Threat Actor Association:** Used by APT1

- **Supported Platforms:** Windows

- **ATT&CK Techniques Used:**
  - T1059 – Command Execution
  - T1071 – Application Layer Protocol

- **Execution Method:** Spear-phishing emails

- **Persistence Techniques:** Registry entries

- **Privilege Escalation:** Exploits vulnerabilities
- **Defense Evasion:** Obfuscation techniques

- **Credential Access:** Steals stored credentials

- **Discovery Techniques:** System and network discovery

- **Lateral Movement:** Moves across network

- **Command & Control (C2):** Remote servers via HTTP

- **Exfiltration:** Sends stolen data

- **Impact Analysis:** Espionage and system control

- **Indicators of Compromise (IOCs):**
  - Suspicious outbound traffic
  - Unknown executables

- **Detection & Mitigation:**
  - Monitor network traffic
  - Use endpoint protection

- **References & Sources:** MITRE ATT&CK

9. HTTPBrowser (S0009)

- **Name & Type:** HTTPBrowser – Malware (Backdoor)

- **Description:** HTTPBrowser is a backdoor used to provide remote access and execute commands through HTTP communication.

- **Threat Actor Association:** Used by APT1

- **Supported Platforms:** Windows

- **ATT&CK Techniques Used:**
  - T1071 – Application Layer Protocol
  - T1105 – Data Transfer

- **Execution Method:** Delivered via phishing or malware

- **Persistence Techniques:** Registry modifications

- **Privilege Escalation:** Uses existing privileges

- **Defense Evasion:** Blends with normal HTTP traffic

- **Credential Access:** Limited

- **Discovery Techniques:** System enumeration

- **Lateral Movement:** Limited

- **Command & Control (C2):** HTTP-based communication

- **Exfiltration:** Sends data via HTTP

- **Impact Analysis:**
  - Remote system access
  - Data theft

- **Indicators of Compromise (IOCs):**
  - Unusual HTTP traffic
  - Unknown processes

- **Detection & Mitigation:**

- Monitor web traffic
- Use firewall rules

– **References & Sources:** MITRE ATT&CK

10. XAgent (S0010)

– **Name & Type:** XAgent – Malware (Spyware / Backdoor)

– **Description:** XAgent is a modular espionage malware used for data theft, surveillance, and remote control.

– **Threat Actor Association:** Used by APT28

– **Supported Platforms:**
  - Windows
  - Linux
  - macOS
  - Mobile platforms

– **ATT&CK Techniques Used:**
  - T1005 – Data Collection
  - T1059 – Command Execution

– **Execution Method:**
  - Phishing emails
  - Malicious links

– **Persistence Techniques:**
  - Registry entries
  - Startup execution

– **Privilege Escalation:** Exploits vulnerabilities

– **Defense Evasion:**
  - Encrypted communication

    - Obfuscation

- **Credential Access:** Captures credentials

- **Discovery Techniques:** System and file discovery

- **Lateral Movement:** Moves within network

- **Command & Control (C2):** Encrypted communication channels

- **Exfiltration:** Sends sensitive data to attacker

- **Impact Analysis:**
    - Long-term espionage
    - Data theft

- **Indicators of Compromise (IOCs):**
    - Suspicious network traffic
    - Unknown background processes

- **Detection & Mitigation:**
    - Use EDR tools
    - Monitor system activity

- **References & Sources:** MITRE ATT&CK
